

## PROBLEMS TO BE SOLVED IN CLASSROOM

### Unit 0. Prerequisites

0.1. Obtain a unit vector perpendicular to vectors  $2\vec{i} + 3\vec{j} - 6\vec{k}$  and  $\vec{i} + \vec{j} - \vec{k}$

*Solution:*

$$(2\vec{i} + 3\vec{j} - 6\vec{k}) \times (\vec{i} + \vec{j} - \vec{k}) = \begin{vmatrix} \vec{i} & \vec{j} & \vec{k} \\ 2 & 3 & -6 \\ 1 & 1 & -1 \end{vmatrix} = 3\vec{i} - 4\vec{j} - \vec{k}$$

$$|3\vec{i} - 4\vec{j} - \vec{k}| = \sqrt{3^2 + 4^2 + 1^2} = \sqrt{26} \quad \vec{u} = \pm \frac{3\vec{i} - 4\vec{j} - \vec{k}}{\sqrt{26}}$$

0.2 a) Find the integral of vector  $\vec{v} = 2xy\vec{i} + 3\vec{j} - 2z^2\vec{k}$  along the straight line parallel to Y axis from point A(1,1,1) to point B(1,3,1) (circulation of a vector along a line).

b) Repeat the above exercise with vector  $\vec{v} = 2xy\vec{i} + 3x\vec{j} - 2z^2\vec{k}$ .

c) If possible, repeat the exercise b) but along the straight line going from A to point C (3,3,1).

*Solution:*

a) Line going from A to B is a straight line parallel to Y axis. Then  $d\vec{r} = dy\vec{j}$

$$\int_A^B \vec{v} d\vec{r} = \int_A^B (2xy\vec{i} + 3\vec{j} - 2z^2\vec{k}) dy\vec{j} = \int_1^3 3 dy = 3(3-1) = 6$$

$$b) \int_A^B \vec{v} d\vec{r} = \int_A^B (2xy\vec{i} + 3x\vec{j} - 2z^2\vec{k}) dy\vec{j} = \int_1^3 3x dy$$

$$\text{As } x \text{ is constant } (x=1) \text{ along the line AB, then } \int_1^3 3x dy = \int_1^3 3 dy = 3(3-1) = 6$$

c) Now, the line going from A to C is not parallel to Y axis, and then  $d\vec{r} = dx\vec{i} + dy\vec{j}$ . Its equation is  $x=y$ . Therefore

$$\begin{aligned} \int_A^C \vec{v} d\vec{r} &= \int_A^C (2xy\vec{i} + 3x\vec{j} - 2z^2\vec{k})(dx\vec{i} + dy\vec{j}) = \int_A^C (2xydx + 3xdy) = \int_1^3 2x^2 dx + \int_1^3 3y dy = \\ &= 2 \frac{x^3}{3} \Big|_1^3 + 3 \frac{y^2}{2} \Big|_1^3 = \frac{2}{3} 26 + \frac{3}{2} 8 = \frac{104+72}{6} = \frac{176}{6} = \frac{88}{3} \end{aligned}$$

0.3 Find the integral of vector  $\vec{v} = 2xy\vec{i} + 3\vec{j} - 2z^2\vec{k}$  through a square with side  $h$  parallel to the plane XY and placed on plane  $z=1$  (integral of a vector through a surface).

*Solution:*

The vector surface of square will be  $d\vec{S} = dS\vec{k}$  (it could be also taken  $d\vec{S} = -dS\vec{k}$ )

$$\int_{\text{square}} \vec{v} d\vec{S} = \int_{\text{square}} (2xy\vec{i} + 3\vec{j} - 2z^2\vec{k}) dS\vec{k} = - \int_{\text{square}} 2z^2 dS$$

$$\text{As the square lays on plane } z=1 \quad - \int_{\text{square}} 2z^2 dS = - \int_{\text{square}} 2 dS = -2 \int_{\text{square}} dS = -2S_{\text{square}} = -2h^2$$

If  $d\vec{S} = -dS\vec{k}$  had been taken, then  $\int_{square} \vec{v} d\vec{S} = 2h^2$  Both results are valid

0.4 Calculate:

- The circulation of vector  $\vec{v} = r\vec{u}_r$  along any circumference having radius 2 and centred at the origin of coordinates.
- The integral of vector  $\vec{v} = r\vec{u}_r$  through a sphere having radius 2 and centred at the origin of coordinates.
- The circulation of vector  $\vec{v} = r\vec{u}_r$  along any radius of sphere between points with  $r=0$  and  $r=2$ .

*Solution:*

- Vector  $\vec{v}$  goes in the direction of radius of circumference and then it is perpendicular to the tangent of circumference at any point. So

$$\int_{circumference} \vec{v} d\vec{r} = 0$$

- Now, vector  $\vec{v}$  is always parallel to surface vector of sphere ( $d\vec{S} = dS\vec{u}_r$ ). Moreover  $r=2$  and so

$$\int_{sphere} \vec{v} d\vec{S} = \int_{sphere} r\vec{u}_r dS\vec{u}_r = \int_{sphere} r dS = 2 \int_{sphere} dS = 2 \cdot 4\pi 2^2 = 32\pi$$

$$c) \int_{radius} \vec{v} d\vec{r} = \int_{radius} r\vec{u}_r dr\vec{u}_r = \int_0^2 r dr = \frac{r^2}{2} \Big|_0^2 = 2$$

## Unit 1: Electrostatics

1.1 a) Calculate the electric field produced at point (4,0) m by two point charges: 2  $\mu\text{C}$  at (0,0) m and -2  $\mu\text{C}$  at (0,3) m. Calculate the force acting over -5  $\mu\text{C}$  placed at point (4,0) m.

b) Repeat the before exercise but at point (4,4) m instead point (4,0) m.

*Solution:*

$$\text{a) } \vec{E}_2 = k \frac{q}{r^2} \vec{u}_r = 9 \cdot 10^9 \frac{2 \cdot 10^{-6}}{4^2} \vec{i} = \frac{9}{8} 10^3 \vec{i} \text{ N/C}$$

$$\vec{E}_{-2} = k \frac{q}{r^2} \vec{u}_r = 9 \cdot 10^9 \frac{2 \cdot 10^{-6}}{5^2} \frac{-4\vec{i} + 3\vec{j}}{5} = \frac{18}{125} 10^3 (-4\vec{i} + 3\vec{j}) \text{ N/C}$$

$$\vec{E}_{(4,0)} = \vec{E}_2 + \vec{E}_{-2} = \frac{9}{8} 10^3 \vec{i} + \frac{18}{125} 10^3 (-4\vec{i} + 3\vec{j}) = 549\vec{i} + 432\vec{j} \text{ N/C}$$

$$\vec{F}_{-5} = -5 \cdot 10^{-6} \vec{E} = -5 \cdot 10^{-6} (549\vec{i} + 432\vec{j}) = -(2745\vec{i} + 2160\vec{j}) \cdot 10^{-6} \text{ N}$$

$$\text{b) } \vec{E}_{(4,4)} = k \frac{2 \cdot 10^{-6}}{32} \frac{(\vec{i} + \vec{j})}{\sqrt{2}} + k \frac{2 \cdot 10^{-6}}{17} \frac{(-4\vec{i} - \vec{j})}{\sqrt{17}} = -629\vec{i} + 141\vec{j} \text{ N/C}$$

$$\vec{F}_{-5} = -5 \cdot 10^{-6} \vec{E} = -5 \cdot 10^{-6} (-629\vec{i} + 141\vec{j}) = (3145\vec{i} - 705\vec{j}) \cdot 10^{-6} \text{ N}$$

1.2 A uniform charged rod of length 14 cm is bent into the shape of a semicircle as shown on picture. The rod has a total charge of -7,5  $\mu\text{C}$ , homogeneously distributed along the rod. Find the magnitude and the direction of the electric field at point O, the centre of the semicircle.

*Solution:*

On this case, the charge is uniformly distributed along the semicircle. Its linear

distribution of charge is:  $\lambda = \frac{Q}{\ell} = -\frac{7,5 \cdot 10^{-6}}{14 \cdot 10^{-2}} = -0,5357 \cdot 10^{-4} \text{ C/m}$

The radius of semicircle is:  $R = \frac{\ell}{\pi} = \frac{14 \cdot 10^{-2}}{\pi} = 4,46 \cdot 10^{-2} \text{ m}$

We'll solve the problem with letters, and at the end we'll change the letters by numbers. If we consider a differential element of semicircle (length  $dl$ ), the charge on this element is:  $dq = \lambda dl$

The electric field produced by this infinitesimal element at point O is:

$$dE = k \frac{\lambda dl}{R^2}$$

being its direction that joining the infinitesimal element and O.

If we consider an infinitesimal element of semicircle symmetric to that on picture, the resulting field of both elements is an horizontal electric field pointing to left whose magnitude is:

$$dE_h = 2k \frac{\lambda dl}{R^2} \cos \varphi$$

And the total electric field at point O is the integral of every infinitesimal elements of semicircle, by taking in account that  $d\ell = R d\varphi$ , is:

$$E_h = \int_0^{\frac{\pi}{2}} 2k \frac{\lambda R d\varphi}{R^2} \cos\varphi = \frac{2k\lambda}{R} \int_0^{\frac{\pi}{2}} \cos\varphi d\varphi = \frac{2k\lambda}{R} = 2,16 \cdot 10^7 \text{ N/C}$$

1.3 Let's take the point charge  $Q$  and the two cubic surfaces, parallel, centered in  $Q$ , and with sides  $a$  and  $3a$ , shown in the figure. Compute the rate between fluxes of the electric field through both surfaces ( $\Phi_a/\Phi_{3a}$ ). Justify the answer.

*Solution:*

$$\Phi_a = \frac{Q}{\epsilon_0}$$

$$\Phi_{3a} = \frac{Q}{\epsilon_0}$$

$$\frac{\Phi_a}{\Phi_{3a}} = 1$$

1.4 A cube of edge  $a$  and uniform volumetric density of charge,  $\rho$ , is placed on vacuum. It's surrounded by a spherical surface of radius  $2a$ . Compute the flux of the electric field through the spherical surface.

*Solution:*

$$\Phi_{2a} = \frac{Q}{\epsilon_0} = \frac{\rho a^3}{\epsilon_0}$$

1.5 Calculate the electric field produced by:

- A spherical surface having radius  $R$  charged with a homogeneous density of charge  $\sigma$ ; calculate the electric field at a distance  $r$  from the centre of sphere for  $r < R$  and  $r > R$ .
- An infinite plane charged with  $\sigma$  homogeneous.
- Two infinite and parallel planes charged with a homogeneous density of charge  $\sigma$ , inside the space between both planes and outside the space (applying superposition). Also consider the case when the charges on both planes have different sign.
- The same exercise as a) but adding a new and negative point charge  $Q$  at the centre of sphere. ¿Could be the electric field zero at any point of the space? ¿In which circumstances?

*Solution:*

- The charge is distributed over the surface, without any charge inside. Therefore, applying Gauss's law to a sphere with radius  $r$ :

$$r < R \quad \Phi = \int_{\text{sphere}} \vec{E} d\vec{S} = E 4\pi r^2 = \frac{0}{\epsilon_0} \Rightarrow E = 0$$

$$r > R \quad \Phi = \int_{\text{sphere}} \vec{E} d\vec{S} = E 4\pi r^2 = \frac{\sigma 4\pi R^2}{\epsilon_0} \Rightarrow E = \frac{\sigma R^2}{\epsilon_0 r^2}$$

$$\text{b) } E = \frac{\sigma}{2\epsilon_0}$$

- If both charges have the same sign:

$$\text{Inside the space between both planes: } E = 0$$

$$\text{Outside the space between both planes: } E = \frac{\sigma}{2\epsilon_0} + \frac{\sigma}{2\epsilon_0} = \frac{\sigma}{\epsilon_0}$$

If both charges have different sign:

$$\text{Inside the space between both planes: } E = \frac{\sigma}{2\epsilon_0} + \frac{\sigma}{2\epsilon_0} = \frac{\sigma}{\epsilon_0}$$

$$\text{Outside the space between both planes: } E = 0$$

$$\text{d) } r < R \quad \Phi = \int_{\text{sphere}} \vec{E} d\vec{S} = E 4\pi r^2 = \frac{Q}{\epsilon_0} \Rightarrow E = \frac{Q}{4\pi\epsilon_0 r^2}$$

$$r > R \quad \Phi = \int_{\text{sphere}} \vec{E} d\vec{S} = E 4\pi r^2 = \frac{\sigma 4\pi R^2 + Q}{\epsilon_0} \Rightarrow E = \frac{\sigma R^2}{\epsilon_0 r^2} + \frac{Q}{4\pi\epsilon_0 r^2}$$

Electric field can only be zero if  $Q = -4\pi\sigma R^2$ . In this case, electric field is zero at any point outside the sphere.

1.6 Calculate:

a) The electric potential at points A (4,0) and B (4,3) produced by the charges of exercise 1.1:  $2 \mu\text{C}$  at (0,0) and  $-2 \mu\text{C}$  at (0,3).

b) The work needed to carry a charge of  $-3 \mu\text{C}$  from A to B.

*Solution:*

$$\text{a) } V_A = 9 \cdot 10^9 \frac{2 \cdot 10^{-6}}{4} - 9 \cdot 10^9 \frac{2 \cdot 10^{-6}}{5} = 18 \cdot 10^3 \left( \frac{1}{4} - \frac{1}{5} \right) = 900 \text{ V}$$

$$V_B = 9 \cdot 10^9 \frac{2 \cdot 10^{-6}}{5} - 9 \cdot 10^9 \frac{2 \cdot 10^{-6}}{4} = 18 \cdot 10^3 \left( \frac{1}{5} - \frac{1}{4} \right) = -900 \text{ V}$$

$$\text{b) } W = q(V_A - V_B) = -3 \cdot 10^{-6} (900 + 900) = 0,0054 \text{ J}$$

1.7 Calculate the d.d.p. (difference of potential) between two points A and B (being d the distance between A and B perpendicularly measured to the plane) of the electric field created by an infinite plane charged with surface density of charge  $\sigma$ .

*Solution:*

$$V_A - V_B = \int_A^B \vec{E} d\vec{r} = Ed = \frac{\sigma d}{2\epsilon_0}$$

1.8 A spherical surface (radius R) is charged with a homogeneous surface density of charge  $\sigma$ . Calculate:

- Electric field on a point placed at a distance  $r$  from the centre of the sphere for  $r < R$  and for  $r > R$ .
- Difference of potential between A(2R) and B(3R).
- Electric potential on point B.
- Difference of potential between C(R/3) and D(R/2).
- Electric potential on points C and D.
- Work done by the electric field to carry a charge  $q$  from B to A.
- Work done by the electric field to carry a charge  $q$  from A to E(2R) (being E a point different than A).
- If  $\sigma$  is positive and we add a negative point charge  $Q$  at the center of sphere, ¿is possible to find a point where the electric field was zero?

1.9 Planes  $y=-1$  and  $y=1$  have surface densities of charge respectively,  $1 \mu\text{C}/\text{m}^2$  and  $2 \mu\text{C}/\text{m}^2$ .

Calculate the difference of potential (d.d.p) between points  $A(0,3,0)$  and  $B(0,5,0)$ , as well as the work needed to move a  $2 \mu\text{C}$  charge from point  $A$  to point  $B$ . ¿Who is doing this work, the forces of the electric field or an external force against the electric field?

*Solution:*

$$V_A - V_B = \int_A^B \vec{E} d\vec{r} = Ed = \left( \frac{1 \cdot 10^{-6}}{2\epsilon_0} + \frac{2 \cdot 10^{-6}}{2\epsilon_0} \right) (5 - 3) = \frac{6 \cdot 10^{-6}}{2\epsilon_0} = \frac{3 \cdot 10^{-6}}{8,85 \cdot 10^{-12}} = 0,339 \cdot 10^6 \text{ V}$$

$W = q(V_A - V_B) = 2 \cdot 10^{-6} \cdot 0,339 \cdot 10^6 = 0,678 \text{ J}$  As this work is positive, the work is done by the forces of electric field.

## Unit 2: Conductors in electrostatic equilibrium. Dielectrics

2.1 Calculate the electric potential created by a conductor sphere (radius  $R$ ) charged with charge  $Q$  at a point placed at a distance  $r > R$  from the centre of sphere. Calculate the electric potential of sphere.

*Solution:*

The electric field at any point outside of sphere comes from Gaus's law:

$$\phi = \int_{\text{sphere}} \vec{E} d\vec{S} = \int_{\text{sphere}} E dS = E \int_{\text{sphere}} dS = E \cdot 4\pi r^2 = \frac{Q}{\epsilon_0} \Rightarrow E = \frac{Q}{4\pi\epsilon_0 r^2}$$

Therefore the electric potential at this point is

$$V = \int_r^\infty \vec{E} d\vec{r} = \int_r^\infty E dr = \int_r^\infty \frac{Q}{4\pi\epsilon_0 r^2} dr = -\frac{Q}{4\pi\epsilon_0 r} \Big|_r^\infty = \frac{Q}{4\pi\epsilon_0 r}$$

The potential of sphere will be

$$V_{\text{sphere}} = V(r = R) = \frac{Q}{4\pi\epsilon_0 R}$$

2.2 Two conductor spheres with radii  $R_1$  and  $R_2$  ( $R_1 > R_2$ ), the first one with charge and the second one without charge are joined with a conductor wire without capacitance (the electric influence between both spheres can be neglected). Calculate the charge and the electric potential of both spheres after the joining.

*Solution:*

Before both spheres are connected, the charge of first sphere is  $Q$  and its potential  $\frac{Q}{4\pi\epsilon_0 R_1}$

When both spheres are connected, then both spheres become the same conductor, and their potentials will be equal. To do it, the second sphere takes a part of charge  $Q$  coming from first sphere. If  $Q_1$  and  $Q_2$  are the charges of both spheres after the connection and  $V$  is their potential, must be verified that:

$$Q_1 + Q_2 = Q \quad \text{and also that} \quad V = \frac{Q_1}{4\pi\epsilon_0 R_1} = \frac{Q_2}{4\pi\epsilon_0 R_2}$$

By solving this system of equations, it comes

$$Q_1 = \frac{QR_1}{R_1 + R_2} \quad Q_2 = \frac{QR_2}{R_1 + R_2} \quad V = \frac{Q}{4\pi\epsilon_0 (R_1 + R_2)}$$

---

Exercises 2.3 to 2.7 must be solved as pieces of the same exercise:

2.3 A point charge  $q$  is placed at a distance  $d$  from the centre of a conductor sphere with radius  $R$  and discharged ( $d > R$ ). Calculate the potential of sphere.

*Solution:*

If we calculate the potential at the centre of sphere:  $V = \frac{q}{4\pi\epsilon_0 d}$

2.4 A point charge  $q$  is placed at the centre of a hollow and conductor sphere (radii  $R_1$  and  $R_2$ ) discharged. Calculate the electric field at the different areas of the space:  $r < R_1$ ,  $R_1 < r < R_2$ ,  $r > R_2$ . Calculate the electric potential of sphere.

*Solution:*

The charge  $q$  induces a charge  $-q$  on inner surface of sphere, and then a charge  $q$  on outer surface of sphere.

$$r < R_1 \quad \phi = E 4\pi r^2 = \frac{q}{\epsilon_0} \Rightarrow E = \frac{q}{4\pi\epsilon_0 r^2}$$

$$R_1 < r < R_2 \quad E = 0$$

$$r > R_2 \quad \phi = E 4\pi r^2 = \frac{q - q + q}{\epsilon_0} = \frac{q}{\epsilon_0} \Rightarrow E = \frac{q}{4\pi\epsilon_0 r^2}$$

$$\text{The electric potential of sphere is } V = \int_{R_2}^{\infty} \vec{E} d\vec{r} = \int_{R_2}^{\infty} E dr = \int_{R_2}^{\infty} \frac{q}{4\pi\epsilon_0 r^2} dr = \frac{q}{4\pi\epsilon_0 R_2}$$

2.5 A point charge  $q$  is placed at a distance  $d$  from the centre of a conductor sphere with radius  $R$  ( $d > R$ ) linked to ground. Calculate the charge of sphere.

*Solution:*

The sphere is linked to ground, and then its potential is null.  $V=0$ . To do it, the sphere takes some charge ( $Q$ ) from ground. The potential of sphere due to both charges is:

$$V = \frac{q}{4\pi\epsilon_0 d} + \frac{Q}{4\pi\epsilon_0 R} = 0 \Rightarrow Q = -\frac{qR}{d}$$

2.6 A point charge  $q$  is placed at the centre of a hollow and conductor sphere (radii  $R_1$  and  $R_2$ ) linked to ground. Calculate the electric field at the different areas of the space:  $r < R_1$ ,  $R_1 < r < R_2$ ,  $r > R_2$ . Calculate the electric potential of sphere.

*Solution:*

The charge  $q$  induces a charge  $-q$  on inner surface of sphere. As the sphere is grounded, the charge on outer surface is null.

$$r < R_1 \quad \phi = E 4\pi r^2 = \frac{q}{\epsilon_0} \Rightarrow E = \frac{q}{4\pi\epsilon_0 r^2}$$

$$R_1 < r < R_2 \quad E = 0$$

$$r > R_2 \quad \phi = E 4\pi r^2 = \frac{q - q}{\epsilon_0} = 0 \Rightarrow E = 0$$

As the sphere is grounded, its electric potential is null.  $V=0$ .

2.7 A hollow sphere (radii  $R_1$  and  $R_2$ ) is linked to ground. A point charge  $q$  is placed at the centre of sphere, and another point charge  $Q$  is placed outside of sphere at a distance  $d$  from its centre ( $d > R$ ). Calculate the total charge of sphere. (In order to solve this exercise, apply the superposition principle taking in account the results of exercises 2.5 and 2.6).

*Solution:*

From exercise 2.5 (outer charge  $Q$ ), the charge on outer surface of sphere is  $-\frac{QR}{d}$  and the charge on inner surface is null.

From exercise 2.6 (charge  $q$  at the centre), the charge on outer surface is null, and charge on inner surface is  $-q$ .

By applying the superposition principle, the total charge of sphere is the charge due to both charges on both surfaces:

$$Q_{total} = -q - \frac{QR}{d}$$

---

2.8 A Van de Graaf generator is made up by a  $10\text{ cm}$  of radius conductor sphere. The generator is transferring electric charge to this sphere from a second smaller sphere having  $5\text{ cm}$  of radius. The distance between both spheres is  $5\text{ mm}$ . By assuming that electric field between the spheres is uniform (really it only changes around 13%) and that the dielectric breaking of the air is produced when the electric field reaches  $1\text{ KV/mm}$ , calculate the charge of each sphere when the spark is produced between the spheres.

*Solution:*

As the charge of big sphere comes from little sphere, both spheres have the same charge (but opposite sign):  $Q$  and  $-Q$ . Therefore the difference of potential between both spheres is (absolute value):

$$|V_{big} - V_{little}| = \frac{Q}{4\pi\epsilon_0 10 \cdot 10^{-2}} + \frac{Q}{4\pi\epsilon_0 5 \cdot 10^{-2}} = Q \cdot 27 \cdot 10^{10}$$

$$\text{On the other hand, this difference of potential must be } |V_{big} - V_{little}| = 1 \cdot 5 = 5\text{ kV} = 5000\text{ V}$$

$$\text{By solving these equations } Q = \frac{5000}{27 \cdot 10^{10}} = 0,02\text{ }\mu\text{C}$$

2.9 A plane conductor (surface  $S$  and negligible thickness) is charged with a charge  $Q$ :

- Let us say how the charge is distributed on conductor, and give its surface density of charge.
- A second equal but discharged conductor plate is approached to the first one up to a little distance compared with the magnitude of both plates (we can then assume total influence between plates). Explain how the charges are distributed on both plates, and give their respective surface densities of charge.

*Solution:*

$$\text{a) The charge } Q \text{ will be distributed across both surfaces of conductor. Then } \sigma = \frac{Q}{2S}$$

- b) If there is total influence between both plates, the charge on that surface facing the first plate will be  $-Q/2$  and then the charge on the other surface will be  $+Q/2$ . In this way, the net charge on second conductor will remain null and the electric field on both conductors is zero.

2.10 A capacitor (capacitance  $C$ ) is connected to a power supply (d.d.p.  $V$  between its plates). Next is disconnected from power supply and it is connected to a second capacitor having capacitance  $2C$ , initially discharged.

- a) Calculate the charge and potential of each capacitor after connecting them.  
b) Plates of second capacitor are approached up to a distance a half of the initial distance. Compute the charge and the difference of potential between plates of each capacitor.

*Solution:*

- a) The charge taken by the first capacitor is  $Q = CV$ . After connecting a second capacitor, this charge is distributed between both capacitors, whose charges will be then  $Q_1$  and  $Q_2$ . On the other hand, the difference of potential between the plates on both capacitors will be equal. These conditions can be written as:

$$Q_1 + Q_2 = Q \quad \text{and} \quad V' = \frac{Q_1}{C} = \frac{Q_2}{2C}$$

$$\text{By solving this system: } Q_1 = \frac{Q}{3} = \frac{CV}{3} \quad Q_2 = \frac{2Q}{3} = \frac{2CV}{3} \quad V' = \frac{1}{3}V$$

- b) Now, the capacitance of second capacitor will be two times the initial capacitance,  $4C$ . We could solve this case in the same way than on before, but we'll now use the equivalent capacitance:  $C_{eq} = C + 4C = 5C$

The charge of equivalent capacitor will be the initial charge  $Q = CV$  and then:

$$V'' = \frac{Q}{C_{eq}} = \frac{CV}{5C} = \frac{V}{5} \quad Q'_1 = CV'' = \frac{1}{5}CV \quad Q'_2 = 4CV'' = \frac{4}{5}CV$$

2.11 Repeat before exercise but keeping the power supply connected every time.

*Solution:*

In this case, the difference of potential between the plates of both capacitors will be  $V$  at any time. So

$$\text{a) } Q_1 = CV \quad Q_2 = 2CV \quad V' = V$$

$$\text{b) } Q'_1 = 2CV \quad Q'_2 = 2CV \quad V'' = V$$

2.12 Two capacitors (capacitance 2 and 3  $\mu F$ ) are connected in series to a 10 V power supply. Compute the charge and the difference of potential between the plates of each capacitor:

- a) Without using the idea of equivalent capacitance of set of capacitors.  
b) By using the idea of equivalent capacitance of set of capacitors.

*Solution:*

- a) As they are connected in series, the charges on both capacitors will be equal ( $Q_1 = Q_2$ ). Moreover, the addition of potentials between the plates of both capacitors will be 10 V:

$$\frac{Q_1}{2 \cdot 10^{-6}} + \frac{Q_2}{3 \cdot 10^{-6}} = 10 \quad Q_1 = Q_2$$

By solving this system:  $Q_1 = Q_2 = 12 \mu C$

And d.d.p.:  $V_1 = \frac{Q_1}{C_1} = \frac{12}{2} = 6 V \quad V_2 = \frac{Q_2}{C_2} = \frac{12}{3} = 4 V$

- b) The equivalent capacitance of both capacitors is

$$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{2} + \frac{1}{3} = \frac{5}{6} \Rightarrow C_{eq} = \frac{6}{5} \mu F$$

The charge  $Q_1 = Q_2 = C_{eq} \cdot 10 = \frac{6}{5} \cdot 10 \cdot 10^{-6} = 12 \mu C$

$$V_1 = \frac{Q_1}{C_1} = \frac{12}{2} = 6 V \quad V_2 = \frac{Q_2}{C_2} = \frac{12}{3} = 4 V$$

2.13 A capacitor with capacitance  $C_0$  is connected to a power supply giving a difference of potential  $V$ . Next, a dielectric with relative dielectric permittivity  $\epsilon_r$  is inserted between the plates of capacitor. Compute the charge and the difference of potential of capacitor after inserting the dielectric. ¿Has the energy stored on capacitor increased or decreased when dielectric is inserted?

*Solution:*

After inserting the dielectric the new capacitance is  $C' = \epsilon_r C_0$  higher than  $C_0$ .

As the power supply isn't disconnected, the difference of potential on capacitor is constant. At any time  $V' = V$  and  $Q' = C'V' = \epsilon_r C_0 V$

The energy stored before and after inserting the dielectric is:

$$W = \frac{1}{2} C_0 V^2 \quad W' = \frac{1}{2} C' V'^2 = \frac{1}{2} \epsilon_r C_0 V^2 > W \quad \text{Stored energy is increased}$$

2.14 A capacitor with capacitance  $C_0$  is connected to a power supply giving a difference of potential  $V$ ; capacitor is disconnected from power supply and a dielectric with relative dielectric permittivity  $\epsilon_r$  is inserted between the plates of capacitor. Compute the charge and the difference of potential of capacitor after inserting the dielectric. ¿Has the energy stored on capacitor increased or decreased when dielectric is inserted?

*Solution:*

Now, as the capacitor is disconnected after its charging, its charge will be constant:

$$Q' = Q = C_0 V \quad V' = \frac{Q'}{C'} = \frac{C_0 V}{\epsilon_r C_0} = \frac{V}{\epsilon_r}$$

The energy stored before and after inserting the dielectric is:

$$W = \frac{1}{2}C_0V^2 \quad W' = \frac{1}{2}C'V'^2 = \frac{1}{2}\epsilon_r C_0 \frac{V^2}{\epsilon_r^2} = \frac{C_0V^2}{2\epsilon_r} < W \quad \text{Stored energy is decreased}$$

2.15 A capacitor with capacitance  $C_0$  is filled with a dielectric having a relative dielectric permittivity 3. Compute the new capacitance of capacitor

a) If it's filled only the left half of space between plates.

b) If it's filled only the lower half of space between plates.

*Solution:*

a) The initial capacitance is  $C_0 = \frac{\epsilon_0 S}{d}$

If only the left half of space is filled with a dielectric, the new capacitor can be considered as two capacitors in series. That on left with capacitance

$$C_1 = \frac{3\epsilon_0 S}{\frac{d}{2}} = \frac{6\epsilon_0 S}{d} = 6C_0$$

And that on right with capacitance  $C_2 = \frac{\epsilon_0 S}{\frac{d}{2}} = \frac{2\epsilon_0 S}{d} = 2C_0$

Then the equivalent capacitance is  $\frac{1}{C'} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{6C_0} + \frac{1}{2C_0} = \frac{4}{6C_0} \Rightarrow C' = \frac{3}{2}C_0$

b) If only the lower half of space is filled with a dielectric, the new capacitor can be considered as two capacitors in parallel.

That's below with capacitance  $C_1 = \frac{3\epsilon_0 \frac{S}{2}}{d} = \frac{3\epsilon_0 S}{2d} = \frac{3}{2}C_0$

And that's above with capacitance  $C_2 = \frac{\epsilon_0 \frac{S}{2}}{d} = \frac{\epsilon_0 S}{2d} = \frac{1}{2}C_0$

Then the equivalent capacitance is  $C'' = C_1 + C_2 = \frac{3}{2}C_0 + \frac{1}{2}C_0 = 2C_0$

### Unit 3: Electric current

3.1 A ring of radius  $R$  has a linear density of charge  $\lambda$ . If the ring turns with an angular speed  $\omega$  around its axis, compute the intensity of current of ring.

*Solution:*

Let's consider a section of ring. Along an infinitesimal time  $dt$  the ring has turned an angle  $d\varphi$ .

So, the angular speed is  $\omega = \frac{d\varphi}{dt}$

Along  $dt$  the considered section has covered a distance  $Rd\varphi$ . The charge on this piece of ring is  $dq = \lambda Rd\varphi$ . As this charge has taken a time  $dt$  to pass through a cross section of ring, the intensity of current is

$$i = \frac{dq}{dt} = \frac{\lambda R d\varphi}{dt} = \lambda R \omega$$

3.2 Along a conductor of Cu with a radius of  $1,3 \text{ mm}$  and length  $1 \text{ m}$ , flows a  $20 \text{ A}$  intensity of current.

a) Compute the density of current  $J$ , the drift speed  $V_d$ , and the time taken by the electrons to cover  $1 \text{ m}$ .  
Data:  $n = 1,806 \cdot 10^{29} \text{ e}^-/\text{m}^3$ ,  $q = 1,6 \cdot 10^{-19} \text{ C}$ .

b) By knowing the resistivity of Cu,  $\rho_{\text{Cu}} = 1,7 \cdot 10^{-8} \Omega \text{m}$ , compute the electric field  $E$  inside the conductor, its resistance  $R$  and the d.d.p. between its endings.

*Solution:*

a) The area of cross section of conductor is  $S = \pi R^2 = \pi (1,3 \cdot 10^{-3})^2 = 5,3 \cdot 10^{-6} \text{ m}^2$

$$J = \frac{I}{S} = \frac{20}{5,3 \cdot 10^{-6}} = 3,8 \cdot 10^6 \text{ A/m}^2$$

$$v_d = \frac{J}{nq} = \frac{3,8 \cdot 10^6}{1,806 \cdot 10^{29} \cdot 1,6 \cdot 10^{-19}} = 0,13 \cdot 10^{-3} \text{ m/s}$$

$$t = \frac{e}{v} = \frac{1}{0,13 \cdot 10^{-3}} = 7,6 \cdot 10^3 \text{ s}$$

$$\text{b) } E = \frac{J}{\sigma} = J\rho = 3,8 \cdot 10^6 \cdot 1,7 \cdot 10^{-8} = 64,6 \cdot 10^{-3} \text{ V/m}$$

$$R = \frac{\rho L}{S} = \frac{1,7 \cdot 10^{-8} \cdot 1}{5,3 \cdot 10^{-6}} = 3,2 \cdot 10^{-3} \Omega$$

$$V = IR = 20 \cdot 3,2 \cdot 10^{-3} = 64 \cdot 10^{-3} \text{ V}$$

3.3 Two  $3 \Omega$  and  $5 \Omega$  resistors are connected in parallel; along the set of resistors is flowing a total intensity of current  $I = 10 \text{ A}$ . Find how much current flows along each resistor.

*Solution:*

If  $I_3$  and  $I_5$  are the intensities flowing along each resistor, we can write:

$$I_3 + I_5 = 10 \quad \text{and} \quad 3I_3 = 5I_5$$

$$\text{By solving this system: } I_3 = \frac{25}{4} \text{ A} \quad I_5 = \frac{15}{4} \text{ A}$$

3.4 Given the set of resistors on picture, find the total intensity  $I$ .

*Solution:*

The equivalent resistor of both  $2\ \Omega$  resistors is  $1\ \Omega$ . Therefore the potential difference between the endings of the whole set of resistors is  $V = 2 \cdot 3 + 2 \cdot 1 = 8\text{ V}$

The intensity flowing along the  $4\ \Omega$  resistor is  $I_4 = \frac{8}{4} = 2\text{ A}$

And the total intensity:  $I = 2 + 2 = 4\text{ A}$

3.5 For both circuits, compute the equivalent resistance between terminals  $A$  and  $B$  ( $R_{AB}$ ) and between terminals  $C$  and  $D$  ( $R_{CD}$ ).

*Solution:*

a) Between  $A$  and  $B$ :

Both  $2\ \Omega$  resistors are connected in parallel, being  $1\ \Omega$  their equivalent resistance. This equivalent resistance is connected in series with  $3\ \Omega$  resistor, being the resulting circuit:

$$\text{Then } \frac{1}{R_{AB}} = \frac{1}{2} + \frac{1}{6} = \frac{2}{3} \Rightarrow R_{AB} = \frac{3}{2}\ \Omega$$

Between  $C$  and  $D$ :

$$\text{Then } \frac{1}{R_{CD}} = \frac{1}{4} + \frac{5}{12} = \frac{8}{12} \Rightarrow R_{CD} = \frac{3}{2} \Omega$$

b) Between A and B:

In this case, the resistors are associated neither in series nor in parallel. But if we pay attention on this circuit we can note that the upper and the lower part of circuit are equal, and then equal intensities will flow along upper and lower branches. For this reason, electric potential on points C and D are equal and then no intensity flows along  $R_3$  resistor. As a consequence  $R_3$  can be removed of circuit and  $R_1$  and  $R_2$  are connected in series both on upper branch as on lower branch.

$$\text{Therefore: } \frac{1}{R_{AB}} = \frac{1}{R_1 + R_2} + \frac{1}{R_1 + R_2} = \frac{2}{R_1 + R_2} \Rightarrow R_{AB} = \frac{R_1 + R_2}{2}$$

Between C and D:

In this case, both  $R_1$  are connected in series and both  $R_2$  are also connected in series. All of them connected in parallel with  $R_3$ . Therefore:

$$\frac{1}{R_{CD}} = \frac{1}{R_1 + R_1} + \frac{1}{R_2 + R_2} + \frac{1}{R_3} = \frac{1}{2R_1} + \frac{1}{2R_2} + \frac{1}{R_3} \Rightarrow R_{CD} = \frac{1}{\frac{1}{2R_1} + \frac{1}{2R_2} + \frac{1}{R_3}}$$

#### Unit 4: Energy and power

4.1 In the circuit of figure, compute:

- Which resistor dissipates more power due to Joule heating?
- Which resistor dissipates less power due to Joule heating?

Justify the answers.

*Solution:*

- The lost power on a resistor is  $P = I^2 R$ . The total intensity is divided between  $R_1$  and  $R_2$  but the total intensity flows through  $R_3$ . Then  $R_2$  and  $R_3$  are the bigger resistors and  $R_2$  is flowed by the higher intensity. So  $R_2$  dissipates more power than the other resistors.
- The resistor dissipating less power should be  $R_1$  or  $R_3$ . The lost power on a resistor is

$$P = \frac{V^2}{R}. \text{ As } V \text{ is the same for both resistors, } R_1 \text{ dissipates less power.}$$

4.2 In the circuit of picture,  $\varepsilon = 6 \text{ V}$  and  $r = 0,5 \Omega$ . Lost power by Joule heating in  $r$  is  $8 \text{ W}$ . Find:

- The intensity of current on circuit.
- The difference of potential between terminals of  $R$ .
- $R$ .
- The generated power, the supplied power, and the efficiency of generator.
- Verify that the supplied power equals the lost power by Joule heating on  $R$ .

*Solution:*

- $8 = I^2 \cdot 0,5 \Rightarrow I = 4 \text{ A}$
- $V_R = \varepsilon - Ir = 6 - 4 \cdot 0,5 = 4 \text{ V}$
- $V_R = IR \Rightarrow 4 = 4 \cdot R \Rightarrow R = 1 \Omega$
- $P_g = \varepsilon I = 6 \cdot 4 = 24 \text{ W}$ 
 $P_s = P_g - I^2 r = 24 - 4^2 \cdot 0,5 = 16 \text{ W}$ 

$$\eta_g = \frac{P_s}{P_g} = \frac{16}{24} = \frac{2}{3} = 0,66 \Rightarrow \eta_g = 66 \%$$
- $P_R = I^2 R = 16 \cdot 1 = 16 \text{ W}$

4.3 A resistor  $R$  is connected to a generator with electromotive force  $\varepsilon$  and internal resistance  $r$ . Which should be the value of  $R$  in order the lost power on this resistor was maximum?

*Solution:*

The current flowing along this circuit is  $I = \frac{\varepsilon}{R+r}$

The lost power on  $R$  is  $P_R = I^2 R = \frac{\varepsilon^2}{(R+r)^2} R$

The maximum of  $P_R$  can be calculated by equalling its derivative to zero:

$$\begin{aligned} \frac{dP_R}{dR} &= \frac{-\varepsilon^2 2(R+r)}{(R+r)^4} R + \frac{\varepsilon^2}{(R+r)^2} = \frac{-\varepsilon^2 2(R+r)R}{(R+r)^4} + \frac{\varepsilon^2 (R+r)^2}{(R+r)^4} = \\ &= \frac{-2\varepsilon^2 R(R+r) + \varepsilon^2 (R+r)^2}{(R+r)^4} = 0 \Rightarrow 2R = (R+r) \Rightarrow R = r \end{aligned}$$

4.4 Compute the difference of potential between points A and B on next pictures:

*Solution:*

a)  $V_A - V_B = 10(20 + 10) - (-10 - 30 + 50) = 300 - 10 = 290 \text{ V}$

b)  $V_A - V_B = -10(5 + 7) - (-10 - 12 + 20) = -120 + 2 = -118 \text{ V}$

c)  $V_A - V_B = 0 \cdot 4 - (-10) = 10 \text{ V}$

d)  $V_A - V_B = 3 \cdot \frac{10}{5} - 1 \cdot \frac{10}{10} = 6 - 1 = 5 \text{ V}$

4.5 The engine of the drawn circuit consumes 50 W, being a 20% by Joule heating. If the generator supplies 100 W to the circuit, compute:

- Consumed power on 50 Ω resistor.
- If the generator generates a power of 110 W, compute their characteristic parameters  $\mathcal{E}$  and  $r$ .
- The characteristic parameters of engine,  $\mathcal{E}'$  and  $r'$ .

*Solution:*

a)  $P_{50} = P_s - P_c = 100 - 50 = 50 \text{ W}$

b)  $P_{50} = 50 = I^2 50 \Rightarrow I = 1 \text{ A} \quad 110 = \mathcal{E} \cdot 1 \Rightarrow \mathcal{E} = 110 \text{ V}$

$P_r = 110 - 100 = 10 = I^2 r = r \Rightarrow r = 10 \Omega$

c)  $P_{r'} = \frac{20 \cdot 50}{100} = 10 = I^2 r' = 1 \cdot r' \Rightarrow r' = 10 \Omega$

$P_t = \frac{80 \cdot 50}{100} = 40 = \mathcal{E}' I = \mathcal{E}' \cdot 1 \Rightarrow \mathcal{E}' = 40 \text{ V}$

4.6 Given the circuit of figure:

a) Compute the magnitude and direction of intensity flowing along circuit.

b) Compute the difference of potential between points A and C ( $V_A - V_C$ ), both along path ABC as along path ADC.

c) Which devices supply energy to the circuit? Compute the value of supplied power by each device.

d) Which devices consume energy from circuit? Compute the value of consumed power by each device.

e) Which are efficiencies of engine and power supply (2)?

f) If we modify the electromotive force of power supply (1), which must be its magnitude for the difference of potential between points A and C equals zero? Which is the intensity on circuit in this case?

*Solution:*

a) If we suppose the intensity flowing on clockwise direction:

$$I = \frac{20 - 10 + 10 - 10}{20 + 100 + 10 + 100 + 10 + 10} = \frac{10}{250} = 0,04 \text{ A}$$

$$b) (V_A - V_C)_{ABC} = 0,04(10 + 100 + 10) - (-10 + 10) = 4,8 \text{ V}$$

$$(V_A - V_C)_{ADC} = -0,04(100 + 20 + 10) - (-20 + 10) = -5,2 + 10 = 4,8 \text{ V}$$

c) Generators 2 and 3 are supplying energy to the circuit because the intensity flows from negative to positive terminal through them.

$$P_{S_2} = \mathcal{E}I - I^2r = 10 \cdot 0,04 - 0,04^2 \cdot 10 = 0,384 \text{ w}$$

$$P_{S_3} = \mathcal{E}I - I^2r = 20 \cdot 0,04 - 0,04^2 \cdot 20 = 0,768 \text{ w}$$

d) Generator 1, Engine and every resistor are consuming energy from circuit.

$$P_{c_1} = \mathcal{E}I + I^2r = 10 \cdot 0,04 + 0,04^2 \cdot 10 = 0,416 \text{ w}$$

$$P_{c_{engine}} = \mathcal{E}'I + I^2r' = 10 \cdot 0,04 + 0,04^2 \cdot 10 = 0,416 \text{ w}$$

$$P_{resistors} = I^2 \sum R_i = 0,04^2 (100 + 100) = 0,32 \text{ w}$$

Of course, the supplied power must be equal to the consumed power:

$$P_S = 0,384 + 0,768 = 1,152 \text{ w}$$

$$P_C = 0,416 + 0,416 + 0,32 = 1,152 \text{ w}$$

$$e) \eta_{engine} = \frac{P_t}{P_c} = \frac{\mathcal{E}'I}{0,416} = \frac{0,4}{0,416} = 0,96 \approx 96 \%$$

$$\eta_2 = \frac{P_{S_2}}{P_{g_2}} = \frac{0,384}{\mathcal{E}I} = \frac{0,384}{10 \cdot 0,04} = 0,96 \approx 96 \%$$

f) If the difference of potential between A and C must be zero, then the intensity of current flowing along the circuit (supposed with the same direction) comes from:

$$(V_A - V_C)_{ADC} = -I(100 + 20 + 10) - (-20 + 10) = 0 \Rightarrow I = \frac{10}{130} \text{ A}$$

If we had supposed the opposite direction for  $I$  we would have obtained a negative intensity.

If we suppose now that the polarity of generator 1 is the same with the new electromotive for, its magnitude comes from:

$$(V_A - V_C)_{ABC} = \frac{10}{130}(10 + 100 + 10) - (-\varepsilon_1 + 10) = 0 \Rightarrow \varepsilon_1 = 0,77 \text{ V}$$

If we had supposed opposite polarity for generator 1, the new electromotive force would result negative.

## Unit 5: Networks

5.1 In the circuit on picture, calculate the intensities in the three branches and the difference of potential between terminals of engine.

*Solution:*

The direction assigned to  $i_3$  means that the upper terminal of engine is the positive terminal, and the lower terminal is the negative. Then, writing Kirchoff's rule of junction A and that of loops for

$$i_1 = i_2 + i_3$$

both loops:  $i_1 \cdot 1 + i_3 \cdot 2 - (10 - 3) = 0$

$$-i_3 \cdot 2 + i_2 \cdot 2 - (3 + 5) = 0$$

By solving this system becomes:  $i_1 = \frac{11}{2} \text{ A}$        $i_2 = \frac{19}{4} \text{ A}$        $i_3 = \frac{3}{4} \text{ A}$

As  $i_3$  is positive, it means that its supposed direction and then the polarity of engine are correct. Therefore

$$V_A - V_B = i_3 \cdot 2 + 3 = \frac{3}{4} \cdot 2 + 3 = \frac{9}{2} \text{ V}$$

5.2 By using Kirchoff's rules, compute the potential on point A and the intensities of current along the branches of circuit on picture.

*Solution:*

If we name  $i_1$  the intensity going from A to B,  $i_2$  that going from A to C and  $i_3$  the intensity from A to D, Kirchoff's rules become:

$$i_1 = i_2 + i_3$$

$$i_1 \cdot 2 + i_3 \cdot 3 - (-5) = 20$$

$$-i_2 \cdot 3 + i_3 \cdot 3 - (-5) = 10$$

By solving this system becomes:  $i_1 = \frac{75}{21} \text{ mA}$        $i_2 = \frac{20}{21} \text{ mA}$        $i_3 = \frac{55}{21} \text{ mA}$

5.3 Along a wire flows an intensity of current 5 A. This wire is divided into two branches: one of them with an ideal generator having a electromotive force 10 V, and another branch with a 5 Ω resistor. After these devices, both branches are joined.

- Compute the intensity of current flowing along each branch.
- Repeat the calculations after inverting the polarity of generator.
- Repeat calculations of points a) and b) by changing the ideal generator by a real generator with internal resistance 10 Ω.

*Solution:*

- The difference of potential on resistor is defined by the battery, 10 V and then, being  $i_1$  the intensity along the 5 Ω resistor (pointing to up):  $5 \cdot i_1 = -10 \Rightarrow i_1 = -2 \text{ A}$

It is, along the resistor flow 2 A to down. Therefore, along the battery flow 7 A to up.

- b) If polarity of generator is inverted:  $5 \cdot i_1 = 10 \Rightarrow i_1 = 2 \text{ A}$  to up. And along the battery flow 3 A to up.
- c) If polarity of generator is that on picture must be verified:

$$i_1 + i_2 = 5 \quad \text{and} \quad 5 \cdot i_1 = 10 \cdot i_2 - 10$$

$$\text{Solution of this system is: } i_1 = \frac{8}{3} \text{ A} \quad i_2 = \frac{7}{3} \text{ A}$$

If polarity of generator is opposite to that on picture:

$$i_1 + i_2 = 5 \quad \text{and} \quad 5 \cdot i_1 = 10 \cdot i_2 + 10$$

$$\text{Solution of this system is: } i_1 = 4 \text{ A} \quad i_2 = 1 \text{ A}$$

5.4 In the network on picture, find the voltage  $V$  so that voltage on junction 1 was 50 V.

*Solution:*

If potential at point 1 is 50 V, then the intensities flowing along both 4 Ω resistors are  $50/4 = 12,5 \text{ A}$  each (going from 1 to ground). So, according to junction's rule, along the middle branch must flow 25 A from ground to junction 1 and must be verified that:

$$50 = -25 \cdot 2 + V \Rightarrow V = 100 \text{ V}$$

5.5 Find the difference of potential between A and B.

*Solution:*

With the intensities shown on picture:

$$i_1 + i_2 + i_3 = 0$$

$$i_1 \cdot 9 - i_2 \cdot 1 - (-12 + 8) = 0$$

$$i_2 \cdot 1 - i_3 \cdot 5 - (-8 + 6) = 0$$

$$\text{By solving the system: } i_1 = -\frac{26}{59} \text{ A} \quad i_2 = \frac{2}{59} \text{ A} \quad i_3 = \frac{24}{59} \text{ A}$$

$$\text{And } V_A - V_B = i_1 \cdot 5 - (-12 + 10) = -\frac{26}{59} \cdot 5 + 2 = \frac{-12}{59} \approx -0,20 \text{ V}$$

5.6 Given the network on picture:

a) Compute the intensities of branches  $I_1$ ,  $I_2$ , and  $I_3$  by means of Kirchhoff's rules.

b) Find the Thevenin's equivalent generator between A and B, clearly showing its polarity.

c) In parallel to points A and B of network, a new  $2\text{ k}\Omega$  resistor is connected. Compute the intensity would flow along this resistor, clearly showing its direction.

*Solution:*

a) With the intensities shown on picture:

$$I_1 + I_2 = I_3$$

$$4I_1 + I_3 - (-3) = 5$$

$$4I_2 + I_3 - (-3) = 5$$

By solving the system:  $I_1 = I_2 = \frac{1}{3}\text{ mA}$   $I_3 = \frac{2}{3}\text{ mA}$

b)  $\mathcal{E}_T = V_{AB} = 4I_1 = \frac{4}{3}\text{ V}$

$R_{eq} = \frac{2}{3}\text{ k}\Omega$

c) 
$$I = \frac{\mathcal{E}_T}{R_{eq} + 2} = \frac{\frac{4}{3}}{\frac{2}{3} + 2} = \frac{1}{2}\text{ mA}$$

## Unit 6: Magnetic forces

6.1 A bundle of electrons move between the plates of a capacitor with a difference of potential  $V$ . Between plates there is a uniform magnetic field perpendicular to the electric field. If plates of capacitor are separated a distance  $d$ , calculate the speed of the electrons not deflecting when they move between plates.

*Solution:*

Electrons not deflected will be those electrons with such speed ( $v_e$ ) that electric force (pointing to up) cancels magnetic force (pointing to down):  $qE = qv_e B$

$$\text{As } E = \frac{V}{d} \text{ therefore: } q \frac{V}{d} = qv_e B \Rightarrow v_e = \frac{V}{Bd}$$

6.2 Let's consider the rectangular loop on picture, with sides  $a$  and  $b$ , and flowed by an intensity  $I$  in the shown direction. The loop is inside a no uniform magnetic field  $\vec{B} = B_0 \frac{a}{x} \vec{k}$ . Calculate the forces acting on sides 1 and 2.

*Solution:*

$$\text{Along side 1, magnetic field is uniform } \vec{B}_1 = B_0 \frac{a}{a} \vec{k} = B_0 \vec{k}$$

$$\text{and the force: } \vec{F}_1 = I b \vec{j} \times B_0 \vec{k} = I b B_0 \vec{i}$$

Along side 2, magnetic field is not uniform, and then we'll consider an infinitesimal piece of conductor  $d\vec{l} = dx \vec{i}$ . The force acting over this piece of conductor is:  $d\vec{F}_2 = I dx \vec{i} \times B_0 \frac{a}{x} \vec{k} = -I B_0 \frac{a}{x} dx \vec{j}$

$$\text{The force over side 2 will be its integral: } \vec{F}_2 = -\int_a^{2a} I B_0 \frac{a}{x} dx \vec{j} = -I B_0 a \ln 2 \vec{j}$$

6.3 By the segment of conductor in the figure flows a current  $I = 2$  A from  $P$  to  $Q$ . It exists a magnetic field  $\vec{B} = 1\vec{k}$  T. Find the total force acting on conductor and prove that it is the same that if the entire conductor was a straight segment from  $P$  to  $Q$ .

*Solution:*

The total force acting on conductor will be the force acting on segment PC plus that acting on segment CQ:

$$\vec{F} = \vec{F}_{PC} + \vec{F}_{CQ} = 2 \cdot 3 \cdot 10^{-2} \vec{i} \times \vec{k} + 2 \cdot 4 \cdot 10^{-2} \vec{j} \times \vec{k} = (-6\vec{j} + 8\vec{i}) 10^{-2} \text{ N}$$

If the entire conductor was a straight segment from  $P$  to  $Q$ , the force acting on it would be:

$$\vec{F}_{PQ} = 2(3 \cdot 10^{-2} \vec{i} + 4 \cdot 10^{-2} \vec{j}) \times \vec{k} = (-6\vec{j} + 8\vec{i}) 10^{-2} \text{ N}$$

6.4 Along conductor AC of figure flows a current of 10 A (it's a part of an electric circuit), being able to glide along two vertical rods.

Compute the necessary uniform magnetic field, perpendicular to the plane of the figure, in order that the magnetic force on conductor could equilibrate the gravitational force. Which should be the direction of magnetic field?

The length of conductor is 10 cm and its mass, 20 g.

*Solution:*

In order the magnetic field can cancel the gravitational force, the magnetic field must exit from paper to the reader. Its magnitude has to verify that:

$$ILB = mg \Rightarrow 10 \cdot 10 \cdot 10^{-2} B = 20 \cdot 10^{-3} \cdot 9,8 \Rightarrow B = 0,196 \text{ T}$$

6.5 Along the loop of the figure of sides  $a$ ,  $b$  and  $c$ , flows an intensity  $I$  in the shown direction. The loop is placed inside a magnetic field  $\vec{B} = B\vec{j}$ .

Find:

- Magnetic forces on sides of the loop.
- Magnetic moment of the loop.
- Torque acting on loop.

*Solution:*

$$\text{a) } \vec{F}_b = I\vec{b}\vec{k} \times B\vec{j} = -IbB\vec{i} \quad \vec{F}_c = Ic\vec{j} \times B\vec{j} = 0$$

$$\vec{F}_a = I(-b\vec{k} + c\vec{j}) \times B\vec{j} = IbB\vec{i}$$

Obviously, as magnetic field is uniform, total force is null.

$$\text{b) } \vec{m} = I\vec{S} = -\frac{Ibc}{2}\vec{i}$$

$$\text{c) } \vec{\tau} = \vec{m} \times \vec{B} = -\frac{Ibc}{2}\vec{i} \times B\vec{j} = -\frac{IBbc}{2}\vec{k}$$

## Unit 7: Sources of Magnetic field

7.1 Two parallel semi-infinite conductors are joined by a semi circumference, as can be seen on picture. Along the set of conductors flows an intensity of current  $I$ . Compute at point O (centre of semi circumference), always giving its direction:

- The magnetic field produced by one of the straight conductors.
- The magnetic field produced by the semi circumference.
- The total magnetic field produced by the set of conductors.

*Solution:*

- $B = \frac{1}{2} \frac{\mu_0 I}{2\pi R}$  Perpendicular to paper and pointing to the reader
- $B = \frac{1}{2} \frac{\mu_0 I}{2R}$  Perpendicular to paper and pointing to the reader
- $B = 2 \frac{1}{2} \frac{\mu_0 I}{2\pi R} + \frac{1}{2} \frac{\mu_0 I}{2R} = \frac{\mu_0 I}{4R} \left( \frac{2}{\pi} + 1 \right)$

7.2 A current weighing scale is made up as is shown on picture:

An horizontal straight conductor 10 cm sized (1) is over the plate of an electronic weighing scale and connected to a second horizontal straight conductor (2), at a distance 2 cm from before conductor (the thickness of conductors can be neglected). Both conductors are connected to a D.C. power supply, making up a circuit. When the power supply is switched on, the reading of weighing scale increases 5.0 mg. (with respect to the reading with the power supply switched off).

- Explain why the reading of weighing scale increases when power supply is switched on.
  - Compute the magnitude of intensity flowing along the circuit when power supply is switched on.
  - Red and black terminals of power supply correspond to its positive and negative terminals. ¿Which would be the reading of weighing scale if we invert the polarity of circuit? (it is, if the intensity would flow in opposite direction).
  - If the power supply can be taken as ideal, and it is supplying 12 V to the circuit, compute the lost power by Joule heating on all the resistors of circuit.
- $\mu_0 = 4\pi \cdot 10^{-7}$  (I.S. units)

*Solution:*

- When power supply is switched on the intensity flows along conductors 1 and 2 in opposite direction. Therefore a rejecting force appears between both conductors and so a higher reading on weighing scale.
- The rejecting force acting on each conductor is:

$$F = ILB = I \cdot 10 \cdot 10^{-2} \frac{\mu_0 I}{2\pi \cdot 2 \cdot 10^{-2}} = I^2 10^{-6} = 5 \cdot 10^{-6} \Rightarrow I = \sqrt{49} = 7 \text{ A}$$

- c) The reading of weighing scale would be the same, because if both intensities change their direction, the force between them is a rejecting force.
- d) The lost power by Joule heating is  $P_J = VI = 12 \cdot 7 = 84 \text{ W}$

7.3 An infinite and straight line conductor is flowed by an intensity  $I_1 = 30 \text{ A}$ . The rectangle  $ABCD$ , whose sides  $BC$  and  $DA$  are parallel to conductor is in the same plane than straight conductor, and it's flowed by an intensity  $I_2 = 10 \text{ A}$ . Compute:

- a) The magnetic flux produced by  $I_1$  through the rectangle.
- b) The force acting on each side of rectangle because of the magnetic field created by  $I_1$ .
- c) Should the resulting force acting on four sides of rectangle be null?

*Solution:*

- a) The magnetic field produced by  $I_1$  at a point over the surface of rectangle, at a distance  $x$  from conductor is:

$$\vec{B} = -\frac{\mu_0 I}{2\pi x} \vec{k} = -\frac{6 \cdot 10^{-6}}{x} \vec{k}$$

The magnetic flux entering on paper is:

$$\phi = \int_{10 \cdot 10^{-2}}^{20 \cdot 10^{-2}} \frac{6 \cdot 10^{-6}}{x} 20 \cdot 10^{-2} dx = 12 \cdot 10^{-7} \int_{10 \cdot 10^{-2}}^{20 \cdot 10^{-2}} \frac{dx}{x} = 12 \cdot 10^{-7} \ln 2 \text{ Wb}$$

$$\text{b) } \vec{F}_{AD} = I_2 \vec{L} \times \vec{B} = 10 \cdot 20 \cdot 10^{-2} \vec{j} \times \left( -\frac{\mu_0 30}{2\pi 10 \cdot 10^{-2}} \vec{k} \right) = -12 \cdot 10^{-5} \vec{i} \text{ N}$$

$$\vec{F}_{BC} = I_2 \vec{L} \times \vec{B} = 10 \cdot (-20 \cdot 10^{-2} \vec{j}) \times \left( -\frac{\mu_0 30}{2\pi 20 \cdot 10^{-2}} \vec{k} \right) = 6 \cdot 10^{-5} \vec{i} \text{ N}$$

$$\vec{F}_{AB} = \int_{10 \cdot 10^{-2}}^{20 \cdot 10^{-2}} I_2 d\vec{x} \times \vec{B} = 10 \int_{10 \cdot 10^{-2}}^{20 \cdot 10^{-2}} \frac{6 \cdot 10^{-6}}{x} dx \vec{j} = 6 \cdot 10^{-5} \ln 2 \vec{j} \text{ N}$$

$$\vec{F}_{CD} = \int_{10 \cdot 10^{-2}}^{20 \cdot 10^{-2}} I_2 d\vec{x} \times \vec{B} = -10 \int_{10 \cdot 10^{-2}}^{20 \cdot 10^{-2}} \frac{6 \cdot 10^{-6}}{x} dx \vec{j} = -6 \cdot 10^{-5} \ln 2 \vec{j} \text{ N}$$

- c) The resulting force shouldn't be null because even though the circuit is a loop, magnetic field over the loop isn't uniform. It can be proved because the summatory of forces along every sides is not null:

$$\vec{F}_{TOTAL} = \vec{F}_{AD} + \vec{F}_{BC} + \vec{F}_{AB} + \vec{F}_{CD} = -6 \cdot 10^{-5} \vec{i} \text{ N} \neq 0$$

## Unit 8: Electromagnetic induction

8.1 A conductor rod with resistance negligible and length  $L$  glides without friction and constant speed  $v$  over a conductor U shaped. The U shaped conductor has a resistance  $R$  and it's placed inside a uniform magnetic field  $\vec{B}$  perpendicular to conductor. Compute:

- Magnetic flux crossing the loop as a function of  $x$ .
- Induced current on the loop, showing its direction.
- Force should act on the rod in order it be displaced at constant speed  $v$ .
- Verify that the power produced by the force computed on c) is lost on resistance as Joule heating.

*Solution:*

- As magnetic field is uniform  $\phi = BLx$
- $\mathcal{E} = \left| \frac{d\phi}{dt} \right| = BL \frac{dx}{dt} = BLv \Rightarrow i = \frac{\mathcal{E}}{R} = \frac{BLv}{R}$  Direction is counterclockwise
- $F = iLB = \frac{BLv}{R} LB = \frac{B^2 L^2 v}{R}$
- $P = Fv = \frac{B^2 L^2 v^2}{R}$   $P_{Joule} = i^2 R = \frac{B^2 L^2 v^2}{R^2} R = \frac{B^2 L^2 v^2}{R}$

8.2 Along an infinite straight carrying current conductor flows an intensity  $I = Kt$  ( $K$  is a positive constant). A rectangular loop with sides  $a$  and  $b$  is placed in the same plane than the conductor, as can be seen on picture. Compute:

- Induced e.m.f. on loop  $\mathcal{E}$ .
- If the loop has a resistance  $R$ , compute the induced current  $i$ , showing its sense.
- Magnetic force acting on side  $AB$  as a function of time,  $F(t)$ .
- Mutual inductance coefficient  $M$  between conductor and loop.

*Solution:*

- Magnetic created by  $I$  at a point placed at a distance  $x$  from wire is:  

$$B = \frac{\mu_0 Kt}{2\pi x}$$
perpendicular to the paper and at points inside the loop, entering on paper.  
Flux through the loop is:  $\phi = \int_c^{c+b} \frac{\mu_0 Kt}{2\pi x} a dx = \frac{\mu_0 Kta}{2\pi} \ln \frac{c+b}{c}$   
And the induced electromotive force:  $\mathcal{E} = \left| \frac{d\phi}{dt} \right| = \frac{\mu_0 Ka}{2\pi} \ln \frac{c+b}{c}$
- $i = \frac{\mathcal{E}}{R} = \frac{\mu_0 Ka}{2\pi R} \ln \frac{c+b}{c}$  Direction is counterclockwise
- $F_{AB} = \int_c^{c+b} i \frac{\mu_0 Kt}{2\pi x} dx = \frac{\mu_0 Ka}{2\pi R} \ln \frac{c+b}{c} \frac{\mu_0 Kt}{2\pi} \int_c^{c+b} \frac{dx}{x} = \left( \frac{\mu_0 K}{2\pi} \ln \frac{c+b}{c} \right)^2 \frac{at}{R}$  perpendicular to  $AB$  and pointing to down

$$d) \quad M = \frac{\phi}{I} = \frac{\mu_0 a}{2\pi} \ln \frac{c+b}{c}$$

8.3 Compute the magnetic flux and the e.m.f. on the square loop of picture; this loop has an area  $S$  and it's turning at constant angular speed  $\omega$  inside a uniform magnetic field  $B$ .

*Solution:*

$$\phi = \vec{B} \cdot \vec{S} = BS \cos \alpha t \quad \varepsilon = \left| \frac{d\phi}{dt} \right| = BS \omega \sin \alpha t$$

8.4 Two ring shaped loops, having radii  $a = 1$  cm and  $b = 50$  cm, are placed concentric in the same plane. If can be supposed that  $a \ll b$  (magnetic field on loop  $a$  due to current on  $b$  can be supposed uniform) compute:

- Mutual induction coefficient between both loops.
- Magnetic flux across loop  $b$  when an intensity  $I = 5$  A sized flows along  $a$ .

*Solution:*

- We'll suppose an intensity of current  $I$  flowing along big loop. Then, the magnetic field produced at points of little loop can be considered as uniform (remember that  $a \ll b$ ). Therefore:

$$\phi_a = BS = \frac{\mu_0 I}{2b} \pi a^2 \quad \text{and} \quad M = \frac{\phi_a}{I} = \frac{\mu_0 \pi a^2}{2b} = 4\pi^2 10^{-11} \text{ H}$$

If we had considered an intensity flowing along little loop, then the supposition that the magnetic field is uniform at points of big loop is not accurate.

$$b) \quad \phi_b = MI = \frac{\mu_0 \pi a^2 I}{2b} = 2\pi^2 10^{-10} \text{ Wb}$$

8.5 The mutual inductance coefficient between circuits on picture is  $M$ . If a current  $i(t) = I_0 \cos(\omega t + \phi)$  flows along circuit 1, which is the intensity flowing along circuit 2?

*Solution:*

The flux through circuit 2 is:  $\phi_2 = Mi(t) = MI_0 \cos(\omega t + \phi)$

$$\text{And the intensity flowing along circuit 2: } i_2(t) = \frac{\varepsilon_2}{R} = \frac{1}{R} \left| \frac{d\phi_2}{dt} \right| = \frac{MI_0 \omega}{R} \sin(\omega t + \phi)$$

8.6 Let's consider two coaxial coils having the same length  $\ell$  but different cross section ( $S_1$  and  $S_2$ ) and different number of turns ( $n_1$  and  $n_2$ ). Coil 2 is placed inside coil 1 ( $S_1 > S_2$ ).

- By supposing an intensity of current  $I_1$  flowing along coil 1, compute the magnetic flux through coil 2 and then the mutual inductance coefficient between both coils.
- By supposing an intensity of current  $I_2$  flowing along coil 2, compute the magnetic flux through coil 1 and then the mutual inductance coefficient between both coils.
- Verify that mutual inductance coefficients computed on a) and b) matches.

Solution:

- a)  $\phi_2 = B_1 S_2 n_2 = \frac{\mu_0 I_1 n_1}{\ell} S_2 n_2$   $M = \frac{\phi_2}{I_1} = \frac{\mu_0 n_1}{\ell} S_2 n_2$
- b)  $\phi_1 = B_2 S_2 n_1 = \frac{\mu_0 I_2 n_2}{\ell} S_2 n_1$   $M = \frac{\phi_1}{I_2} = \frac{\mu_0 n_2}{\ell} S_2 n_1$
- c) Both mutual inductance coefficients match.

8.7 Compute the self inductance coefficient of a coil having length  $\ell$ , cross section  $S$  and  $n$  turns.

Solution:

If we suppose an intensity of current  $I$  flowing along coil, the magnetic field inside the coil is:

$$B = \mu_0 I \frac{n}{\ell} \quad \text{and the flux} \quad \phi = BS = \mu_0 I \frac{n}{\ell} S$$

Therefore the self-inductance coefficient is  $L = \frac{\phi}{I} = \frac{\mu_0 n^2 S}{\ell}$

8.8 Let's take a coil with a self-inductance coefficient  $L = 2 \text{ H}$  and a resistance  $R = 12 \Omega$ .

- a) If an intensity of current  $I=3t$  ( $t$  is the time) is flowing from A to B, compute the difference of potential  $V_A - V_B$  at time  $t=1 \text{ s}$ .

- b) If an intensity of current  $I=10-3t$  ( $t$  is the time) is flowing from A to B, compute the difference of potential  $V_A - V_B$  at time  $t=1 \text{ s}$ .

The coil is connected to an ideal generator with an electromotive force  $\varepsilon = 24 \text{ V}$  (fig.(a)):

- c) When the steady state is got, remaining constant the intensity of current, compute the intensity of current flowing along the circuit.

- d) Compute the stored energy on coil.

- e) If the coil is short-circuited and generator is removed (fig. (b)) ¿Which is the lost energy as heating on coil due to its resistance?

Solution:

- a)  $V_A - V_B = IR + L \frac{dI}{dt} = 3t \cdot 12 + 2 \cdot 3 = 36t + 6$   
 On time  $t=1 \text{ s}$   $(V_A - V_B)_1 = 42 \text{ V}$
- b)  $V_A - V_B = IR + L \frac{dI}{dt} = (10 - 3t) \cdot 12 + 2 \cdot (-3) = -36t + 114$   
 On time  $t=1 \text{ s}$   $(V_A - V_B)_1 = 78 \text{ V}$
- c)  $I = \frac{24}{12} = 2 \text{ A}$

d)  $W = \frac{1}{2}LI^2 = \frac{1}{2}2 \cdot 2^2 = 4 \text{ J}$

e)  $W = 4 \text{ J}$

### Unit 9: Alternating current

9.1 A resistor  $5\ \Omega$  sized, an inductor  $10\text{ mH}$  sized, and a capacitor  $50\ \mu\text{F}$  sized, are connected in series. The voltage on terminals of inductor is  $u_L(t) = 100\cos(1000t + \frac{\pi}{4})\text{ V}$ . Compute the intensity of current flowing along three dipoles, the voltage on terminals of resistor and capacitor and the voltage on terminals of RLC dipole.

*Solution:*

The intensity of current (equal for three dipoles) can be calculated from voltage on terminals of inductor:

$$X_L = L\omega = 10 \cdot 10^{-3} \cdot 10^3 = 10\ \Omega \quad I_m = \frac{U_{Lm}}{X_L} = \frac{100}{10} = 10\text{ A}$$

Phase lag on an inductor is  $\pi/2$  ( $90^\circ$ ):  $\varphi = 90^\circ = \varphi_u - \varphi_i = 45 - \varphi_i \Rightarrow \varphi_i = 45 - 90 = -45^\circ$

Therefore: 
$$i(t) = 10\cos(1000t - 45^\circ)\text{ A}$$

On capacitor: 
$$X_C = \frac{1}{C\omega} = \frac{1}{50 \cdot 10^{-6} \cdot 10^3} = 20\ \Omega \quad U_{Cm} = I_m X_C = 10 \cdot 20 = 200\text{ V}$$

$$\varphi = -90^\circ = \varphi_u - \varphi_i = \varphi_u + 45 \Rightarrow \varphi_u = -90 - 45 = -135^\circ$$
$$u_C(t) = 200\cos(1000t - 135^\circ)\text{ V}$$

On resistor: 
$$U_{Rm} = I_m R = 10 \cdot 5 = 50\text{ V} \quad u_R(t) = 50\cos(1000t - 45^\circ)\text{ V}$$

On the whole dipole (RLC): 
$$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{5^2 + (10 - 20)^2} = 11,18\ \Omega$$

$$U_m = I_m Z = 10 \cdot 11,18 = 111,8\text{ V} \quad \text{tg } \varphi = \frac{X_L - X_C}{R} = \frac{10 - 20}{5} = -2 \Rightarrow \varphi = -63,4^\circ$$
$$-63,4^\circ = \varphi_u - \varphi_i = \varphi_u + 45 \Rightarrow \varphi_u = -63,4 - 45 = -108,4^\circ$$

Therefore: 
$$u(t) = 111,8\cos(1000t - 108,4^\circ)\text{ V}$$

9.2 A circuit is made up by two basic dipoles in series. The terminals of this circuit are connected to an A.C. generator giving a voltage  $u(t) = 150\cos(500t + 10^\circ)\text{ V}$ , and flowing along the circuit an intensity of current  $i(t) = 13,42\cos(500t - 53,4^\circ)\text{ A}$ . Determine the two basic dipoles and their magnitudes.

*Solution:*

The phase lag on dipole is: 
$$\varphi = \varphi_u - \varphi_i = 10 - (-53,4) = 63,4^\circ$$

As phase lag is positive and not equal to  $90^\circ$ , it means that the dipoles on circuit are an inductor and a resistor.

$$\text{tg } 63,4^\circ = 2 = \frac{X_L}{R} \Rightarrow X_L = L\omega = 2R$$

$$Z = \frac{150}{13,42} = 11,18 = \sqrt{R^2 + X_L^2} = \sqrt{R^2 + 4R^2} = R\sqrt{5} \Rightarrow R = \frac{11,18}{\sqrt{5}} = 5 \, \Omega$$

And  $L = \frac{2R}{\omega} = \frac{10}{500} = 20 \, mH$

## Unit 10 Resonance and filters.

10.1 Represent on a graph the drawing of intensity of current, voltage on resistor, voltage on inductor, voltage on capacitor and voltage on terminals of a  $RLC$  series circuit having a resistor  $5\ \Omega$  sized, a  $10\text{ mH}$  inductor and a  $100\ \mu\text{F}$  capacitor. The amplitude of intensity is  $10\text{ A}$ , initial phase of intensity can be taken zero, and as angular frequency must be used that corresponding to the resonant angular frequency.

*Solution:*

The resonant angular frequency is:

$$\omega_0 = \sqrt{\frac{1}{LC}} = \sqrt{\frac{1}{10 \cdot 10^{-3} \cdot 100 \cdot 10^{-6}}} = 1000\text{ rad/s}$$

With this angular frequency, the amplitude and phase lag of voltage on every device is:

Resistor:  $U_{Rm} = I_m R = 10 \cdot 5 = 50\text{ V}$        $\varphi = 0 \Rightarrow \varphi_u = \varphi_i = 0$

Inductor:  $X_L = L\omega_0 = 10 \cdot 10^{-3} \cdot 10^3 = 10\ \Omega$        $U_{Lm} = I_m X_L = 10 \cdot 10 = 100\text{ V}$

$$\varphi = 90^\circ = \varphi_u - \varphi_i \Rightarrow \varphi_u = 90^\circ + \varphi_i = 90^\circ$$

Capacitor:  $X_C = \frac{1}{C\omega_0} = \frac{1}{100 \cdot 10^{-6} \cdot 10^3} = 10\ \Omega$        $U_{Cm} = I_m X_C = 10 \cdot 10 = 100\text{ V}$

$$\varphi = -90^\circ = \varphi_u - \varphi_i \Rightarrow \varphi_u = -90^\circ + \varphi_i = -90^\circ$$

RLC series circuit:  $Z = \sqrt{R^2 + (X_L - X_C)^2} = R = 5\ \Omega$        $\varphi = 0 = \varphi_u - \varphi_i \Rightarrow \varphi_u = 0$

Therefore, drawing of intensity and voltages is:

10.2 Using the circuit of exercise 10.1, represent on a graph the active and reactive powers on resistor, inductor and capacitor, as well as their average values in resonance.

*Solution:*

Reactive power on resistor and active powers on inductor and capacitor are zero; their average values are also zero as well as average reactive power on inductor and capacitor.

The powers not being zero are:

Active power on resistor:  $P_a(t) = I_m^2 R \sin^2 \omega_0 t = 500 \sin^2 1000 t \text{ w}$

$$P_{aav} = \frac{1}{2} I_m^2 R = 250 \text{ w}$$

Reactive power on inductor:  $P_r(t) = \frac{1}{2} I_m^2 L \omega_0 \sin 2\omega_0 t = 500 \sin 2000 t \text{ w}$

Reactive power on capacitor:  $P_r(t) = -\frac{I_m^2}{2C\omega_0} \sin 2\omega_0 t = -500 \sin 2000 t \text{ w}$

Drawing a graph with these magnitudes results:

### Unit 11: Semiconductor materials

10.1 Find the density of electrons and holes on Ge on following circumstances:

- a) Pure Ge at 300 K ( $n_i(300\text{ K}) = 2,36 \cdot 10^{19} \text{ m}^{-3}$ )
- b) At 300 K doped with Sb (antimony) with a concentration of  $N_D = 4 \cdot 10^{22} \text{ m}^{-3}$
- c) At 300 K doped with In (indium) with a concentration of  $N_A = 3 \cdot 10^{22} \text{ m}^{-3}$
- d) Pure Ge at 500 K ( $n_i(500\text{ K}) = 2,1 \cdot 10^{22} \text{ m}^{-3}$ )
- e) At 500 K doped with Sb with a concentration of  $N_D = 3 \cdot 10^{22} \text{ m}^{-3}$ .
- f) At 500 K doped with In with a concentration of  $N_A = 4 \cdot 10^{22} \text{ m}^{-3}$

*Solution:*

- a) As Ge is pure,  $n = p = n_i = 2,36 \cdot 10^{19} \text{ e} - \text{h} / \text{m}^3$
- b) As concentration of donor impurities is much higher than intrinsic concentration  
( $4 \cdot 10^{22} \gg 2,36 \cdot 10^{19}$ )  $n \approx N_D = 4 \cdot 10^{22} \text{ e} / \text{m}^3$   $p = \frac{n_i^2}{n} \approx 1,39 \cdot 10^{16} \text{ h} / \text{m}^3$
- c) As concentration of acceptor impurities is much higher than intrinsic concentration  
( $3 \cdot 10^{22} \gg 2,36 \cdot 10^{19}$ )  $p \approx N_A = 3 \cdot 10^{22} \text{ h} / \text{m}^3$   $n = \frac{n_i^2}{p} \approx 1,86 \cdot 10^{16} \text{ e} / \text{m}^3$
- d)  $n = p = n_i = 2,1 \cdot 10^{22} \text{ e} - \text{h} / \text{m}^3$
- e) At 500 K, the concentration of impurities and intrinsic concentration are of the same order and the density of electrons and holes must be calculated by solving the equation system:

$$\begin{cases} p \cdot n = n_i^2 \\ n = N_D + p \end{cases} \Rightarrow \begin{cases} p \cdot n = (2,1 \cdot 10^{22})^2 \\ n = 3 \cdot 10^{22} + p \end{cases}$$

$$\text{whose solution is: } n = 4,08 \cdot 10^{22} \text{ e} / \text{m}^3 \quad p = 1,08 \cdot 10^{22} \text{ h} / \text{m}^3$$

$$\text{f) } \begin{cases} p \cdot n = n_i^2 \\ N_A + n = p \end{cases} \Rightarrow \begin{cases} p \cdot n = (2,1 \cdot 10^{22})^2 \\ 4 \cdot 10^{22} + n = p \end{cases}$$

$$\text{whose solution is: } n = 2,1 \cdot 10^{22} \text{ e} / \text{m}^3 \quad p = 4,9 \cdot 10^{22} \text{ h} / \text{m}^3$$

## Unit 12: Semiconductor devices

11.1 On circuit on picture, compute the voltage at output ( $V_s$ ) as well as the intensities of current flowing along both diodes. Diodes  $D_1$  and  $D_2$  are diodes built with Si (drop forward voltage  $V_u=0,7$  V).

*Solution:*

$D_1$  is forward biased and  $D_2$  is reverse biased. Their internal resistances are neglected.

Therefore

$$V_s = 10 - 0,7 = 9,3 \text{ V} \quad I_1 = \frac{9,3}{1} = 9,3 \text{ mA} \quad I_2 = 0$$

11.2 On circuit on picture both diodes have drop forward voltage  $V_u=0,7$  V, and internal resistance can be neglected. Compute:

- Intensities  $I_1$  e  $I_2$  flowing along diodes  $D_1$  and  $D_2$ .
- Potential difference  $V_A - V_B$  between terminals of diode  $D_2$ .

*Solution:*

- $D_1$  is forward biased and  $D_2$  is reverse biased.

Internal resistances are neglected. Therefore

$$I_1 = \frac{6 - 0,7}{5} = \frac{5,3}{5} = 1,06 \text{ mA clockwise direction} \quad I_2 = 0$$

- $V_A - V_B = I_2 \cdot 5 - I_1 \cdot 5 = -5,3 \text{ V}$
