Motivation

- Problem solution with a program sometimes requires a repeated execution of a sequence of instructions
- Number of repetitions can be known *a priori* or not
- *Examples:*
 - Sum all the values of a list
 - Calculate the sum of the first n natural numbers
 - Check if a word exists in a dictionary
 - Ask the user for a value in a range
 - Code a text changing all its letters
 - . . .

Motivation

- Programming languages have repetition instructions: *loops*
- Loops allow to repeat a sequence of instructions as many times as needed
- Basically, a block of instructions (*body*) is *repeated while* a *condition* (*guard*) is true
- *Iteration* or loop execution: any time the body is executed
- *Loop*: set of instructions executed until an exit condition appears

Iteration

- A problem solution must accomplish the following conditions:
 - Its instructions must be described in a finite manner
 - Its execution must be finite
- Many simple problems require only simple sequences of instructions
- Other problems require some instructions to be repeated many times
- If repetition is needed, when solving the problem we must:
 - Detect instruction patterns that are repeated
 - Express the solution by using the detected patterns and repeat instructions

Iteration

- For example, multiply a number a by n using repeated sums (suposing n is not negative)

$$\begin{array}{ll} a*n == \underbrace{a + a + a + \dots + a}_n & \text{if } n>0 \\ a*n == 0 & \text{if } n==0 \end{array}$$

$$a*n == 0 + \underbrace{a + a + a + \dots + a}_n$$

Iteration

- Solution uses an auxiliar var `acc`, which in each iteration takes the values:

$0*a$	Iteration 0
$1*a$	Iteration 1
$2*a$	Iteration 2
\dots	
$n*a$	Iteration n

- In each iteration, `acc` is updated according to

$$\text{acc} = \text{acc} + a;$$

- Repetition pattern: in the i th iteration, the value of `acc` is actually $i*a$

Iteration Elements

In each loop there are three main basic structural components:

- ***Guard of the loop***: condition that while it is evaluated to true makes the body of the loop (sequence of instructions) to be executed
- ***Body of the loop***: sequence of instructions that allows to arrive step by step towards the solution of the problem
- ***Variable initialisation***: before the loop, the vars that are involved in its execution must have a correct value

Iteration Elements

- Taking into account those elements, the usual structure of iteration is:

variable initialisation
while guard of the loop
body of the loop

- In Java syntax, this is transcribed into:

```
variable initialisation;  
while (guard of the loop) {  
    body of the loop;  
}
```

Iteration Elements

Multiplication by sum example:

```
public static int mult(int a, int n) {  
    int acc, numIt;  
  
    // Variable initialisation  
    acc = 0;  
    numIt= 0;  
  
    while (numIt<n) { // Guard of the loop  
        // Body of the loop  
        acc = acc + a;  
        numIt++;  
    }  
  
    return acc;  
}
```

Notice the use of numIt to express the termination/continuation of the loop

Iterative instructions in Java: while loop

```
while (condition)  
    instruction;
```

```
while (condition) {  
    instruction_1;  
    instruction_2;  
    ...  
    instruction_n;  
}
```

Iterative instructions in Java: while loop

while loops are usually used for *a priori* unknown number of iterations

E.g.: read integer numbers until a 0 appears, show the sum of all

```
int i, s=0;

i=kbd.nextInt();
while (i!=0) {
    s+=i;
    i=kbd.nextInt();
}

System.out.println("Total sum: "+s);
```

Iterative instructions in Java: for loop

Execution

1. Execute the initialisation instructions
2. Evaluate condition
3. When it is false, go to step 6
4. Execute the instructions of the body
5. Execute update instructions, go to step 2
6. Continue with the instruction that follows the loop

Iterative instructions in Java: for loop

Syntax:

```
for ([initialisation]; [condition]; [update])  
    instruction;
```

```
for ([initialisation]; [condition]; [update]) {  
    instruction_1;  
    ...  
    instruction_n;  
}
```

- Parts between brackets (`[]`) are optional
- **Condition**: boolean expression (no condition is evaluated to true)
- **Initialisation**: init of the loop; typically *counter=value* (*i=0*)
- **Update**: progression of the loop; typically *counter=newVal* (*i=i+1, i++*)

initialisation and update could be lists of elements separated by commas (,) (e.g.,
i=0,j=0,k=3 i++,j+=2,k--)

Iterative instructions in Java: for loop

The for loop:

```
for ([i1,i2,...,in]; [condition]; [u1,u2,...,un])  
    instruction;
```

It is equivalent to the following while loop:

```
[i1;i2;...;in;]           // Initialization  
while (condition) {  
    instruction;  
    [u1;u2;...;un;]       // Update  
}
```

Iterative instructions in Java: for loop

for loops are usually used for a known number of iterations

E.g.: read ten real numbers and show the mean

```
double num, sum=0.0;  
int i;
```

```
for (i=0;i<10;i++) {  
    num=kbd.nextDouble();  
    sum+=num;  
}
```

```
System.out.println("Mean: "+sum/10);
```

Iterative instructions in Java: do - while loop

Execution

1. Execute the instructions of the body of the loop until condition is false
2. The execution continues with the instruction that follows the loop

The instructions of the body of the loop get executed at least once

Iterative instructions in Java: do - while loop

Its general form is:

```
do
    instruction;
while (condition);
```

```
do {
    instruction_1;
    instruction_2;
    ...
    instruction_n;
} while (condition);
```

where `condition` is any boolean condition (guard of the loop) and the body of the loop is an instruction or a block of instructions

Iterative instructions in Java: do - while loop

- Differences between while and do-while loops:
 - Since in do-while the guard is evaluated after executing the body, at least the first iteration is executed in this loop
 - Syntax restriction: in do-while, a ; must appear after (condition)
- Any problem expressed with a do - while loop can be expressed with a while loop and vice-versa, writing the auxiliary needed instructions

```
initial_instructions;  
while (condition) {  
    body_of_the_loop;  
}  
following_instructions;
```

```
initial_instructions;  
if (condition)  
    do {  
        body_of_the_loop;  
    } while (condition);  
following_instructions;
```

Iterative instructions in Java: do - while loop

do-while loop is usually used for validating inputs

E.g.: read an age (must be non-negative)

```
int age;  
  
do {  
    System.out.print("Input your age: ");  
    age=kbd.nextInt();  
} while (age<0);
```

- 4 Iterative instructions in Java: for loop ▷ 16
- 5 Iterative instructions in Java: do - while loop ▷ 21
- 6 *Nested loops* ▷ 26
- 7 Theoretical aspects of iteration ▷ 30

Nested loops

Loops can be inside other loops, which form *nested loops*

In this case, the different guards must not interfere

E.g.: read ten valid ages and show the average age:

```
int i, age, sum=0;

for (i=0;i<10;i++) {
    do {
        System.out.print("Input your age: ");
        age=kbd.nextInt();
    } while (age<0);
    sum+=age;
}

System.out.println("Mean age: "+sum/10);
```

Nested loops

E.g.: generate sequences of four random real numbers between 0 and 1 until they sum more than 0.8

```
double x, sum=0.0;
int i;

while (sum<=0.8) {
    sum=0.0;
    for (i=0;i<4;i++) {
        x=Math.random();
        sum+=x;
    }
}
```

Nested loops

E.g.: show the multiplication table for numbers from 1 to 10

```
int i, j;

for (i=1;i<=10;i++) {

    System.out.println("Table for number "+i);
    System.out.println("-----");

    for (j=1;j<=10;j++)
        System.out.println(i+" X "+j+" = "+(i*j));

    System.out.println();

}
```

- 6 Nested loops ▷ 26
- 7 *Theoretical aspects of iteration* ▷ 30

Theoretical aspects of iteration

Important details to take into account when a loop is implemented:

A Define the *loop invariant*

Define the repetitive structure from a property that is fulfilled at the end of each iteration, and that by the end of the loop guarantees the desired effect; this property is the loop invariant

Loop invariant is used to prove *correctness*

B Guarantee the *termination*

The stop condition is the negation of the guard; the vars used in the guard are modified in the body in a way that will make the loop stop

Termination guarantees *finiteness*

Theoretical aspects of iteration

The multiplication by sum example

```
public static int mult(int a, int n) {  
    int acc, nI;  
  
    // Variable initialisation  
    acc = 0;  
    nI = 0;  
  
    while (nI < n) { // Guard of the loop  
        // Body of the loop  
        acc = acc + a;  
        nI++;  
    }  
  
    return acc;  
}
```

- Invariant
 - The invariant is that in the i th iteration, acc has a value equal to $a * nI$
 - Thus, when nI equals to n , acc equals to $a * n$, which was the desired value
- Termination
 - When finishing the i th iteration, $acc == a * nI$
 - The loop must stop when nI equals to n
 - Stop condition: $nI == n$
 - Guard: $nI != n$

Theoretical aspects of iteration

The GCD example

- Let consider the example of obtaining the Greatest Common Divisor (GCD) of two integer numbers A and B greater than 0
- Implementation of the Euclides algorithm (300 b.C.)
- GCD algorithm: let vars a and b take as initial values A and B, and then
 1. If a is equal to b stop, any of them is the GCD
 2. If $a > b$, make a equal to $a - b$,
in other case make b equal to $b - a$
 3. Go to 1
- In Java code:

```
public static int gcd(int a, int b) {  
    while (a != b)  
        if (a > b) a = a - b; else b = b - a;  
    return a;  
}
```

Theoretical aspects of iteration

The GCD example

A The invariant property is given by:

- By the end of each iteration, $\text{GCD}(A,B) = \text{GCD}(a,b)$, where A and B represent the initial values of a and b
- This property is a consequence of the mathematical property

$$\text{GCD}(a, b) = \text{GCD}(a - b, b) \quad a > b > 0$$

Theoretical aspects of iteration

The GCD example

B Termination: does always the execution stops? does it always arrive to the point where $a==b$?

Yes, because:

- a and b are always different from 0
- The value $|a-b|$ becomes lower in each iteration and it is never lower than 0

Proving termination generally requires defining a function (boundary function)

Boundary function must accomplish:

- The more loop iterations, the lower its value becomes
- It is bounded
